

# CLASSWMS GUI

## HELP DOCUMENTATION

*CLASSWMS is a Graphical User Interface developed under MATLAB, to classify water masses using clustering analysis and KNN classifier, according to the process presented by (Ayoub BELATTMANIA et al 2023).*

Elaborated by: Ayoub BELATTMANIA  
September 2023

## 1. OVERVIEW

The classwms tool enables geoscientists, particularly oceanographers, to classify water masses automatically on the basis of hydrological profiles gathered in situ. The application consists of two classification methods:

- The clustering analysis:

This approach is employed on a T-S diagram and relies on the iterative k-means algorithm, a conventional method used to define the characteristics of water masses. To assess the effectiveness of the clustering analysis, users have the option to calculate the silhouette coefficient.

- K Nearest Neighbors Classification:

The method, extensively explained in the investigation by Ayoub BELATTMANIA et al 2023, relies on a novel supervised classification approach applied to the potential density and potential spicity ( $\sigma$ - $\pi$ ) diagram.

## 2. USAGE AND SUPPORT MATERIAL

The utilization of the classwms GUI mandates the presence of MATLAB R2021a version or higher. To use the tool, individuals can obtain the required files from GitHub: <https://github.com/AYOUBELATTMANIA/classwms.git>. This pertains specifically to the source code and accompanying support materials.

To start using the classwms GUI, users need to rename the downloaded folder from the aforementioned GitHub link to 'classwms' and subsequently transfer it to C drive (C:).

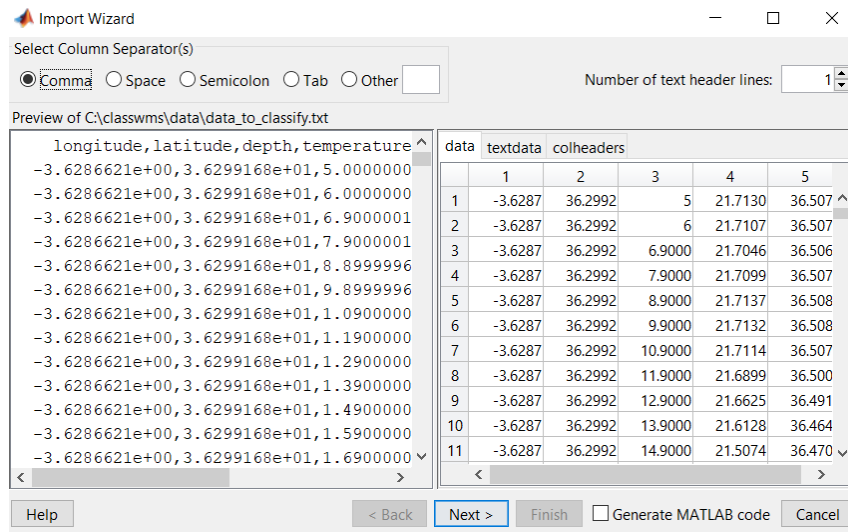

## 3. MAIN FUNCTIONALITIES

### **Import data**

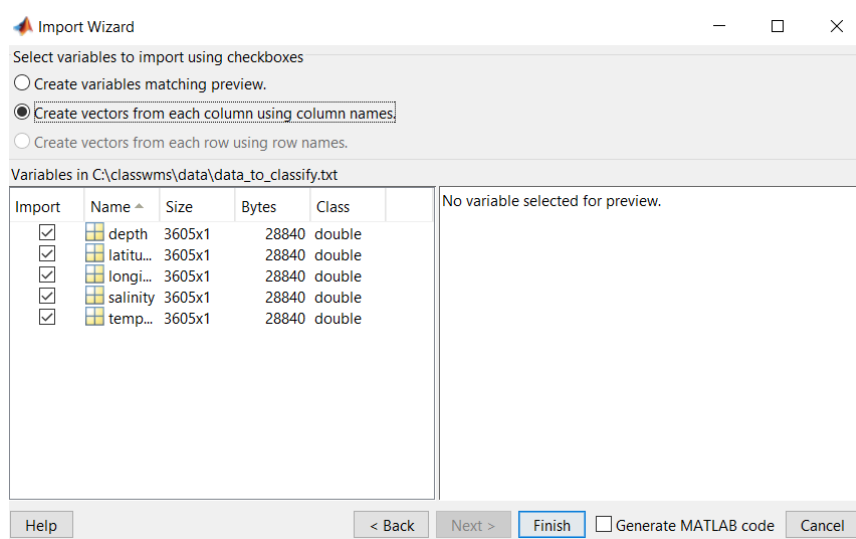

This option is used to import the data file that the user wishes to classify. This file, called 'data\_to\_classify.txt', contains the following fields: longitude, latitude, depth, temperature and salinity. Outliers must be replaced with NaNs. Here are the steps involved in this operation:

- **Separator selection**

The screenshot shows the 'Import Wizard' dialog box. Under 'Select Column Separator(s)', the 'Comma' radio button is selected. The 'Number of text header lines' is set to 1. The 'Preview' section shows the raw data from 'C:\classwms\data\data\_to\_classify.txt' as a single line of comma-separated values. To the right, a table preview shows the data organized into columns: 'data', 'textdata', 'colheaders', and five unnamed columns numbered 1 to 5. The 'Next >' button is highlighted.

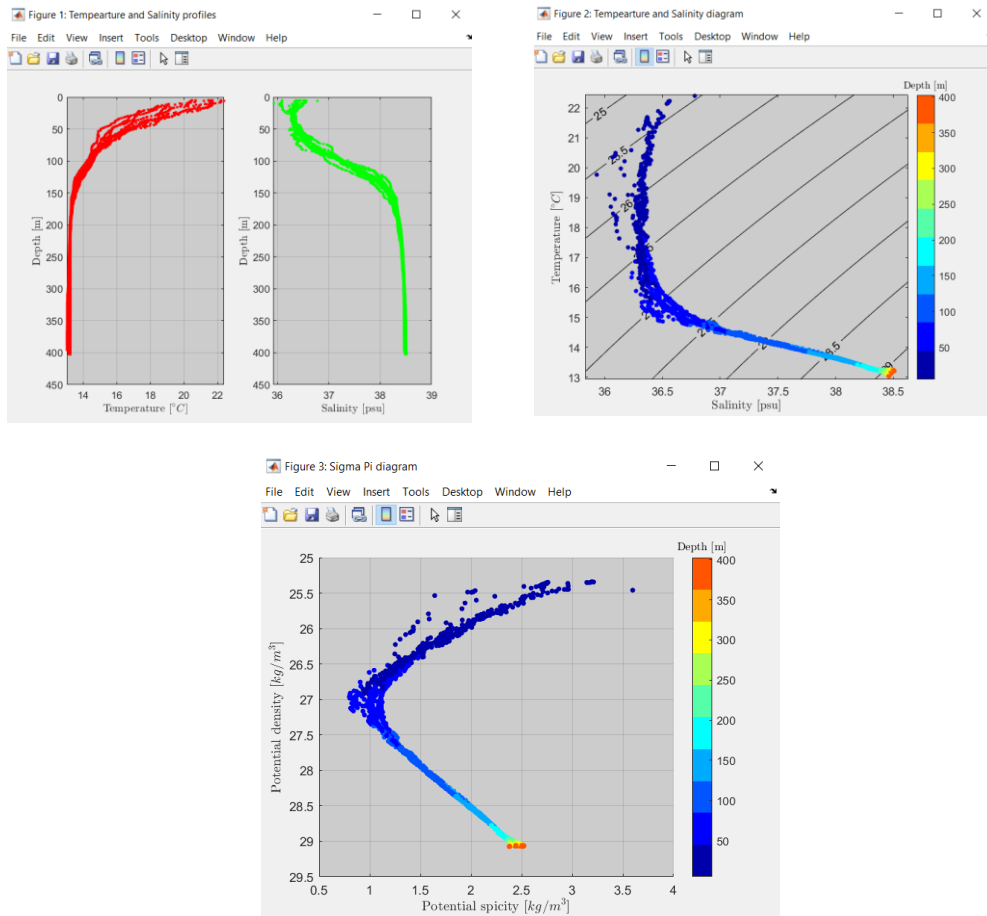

- **Assigning columns to fields**

The screenshot shows the 'Import Wizard' dialog box at the 'Assigning columns to fields' step. The option 'Create vectors from each column using column names' is selected. Below, a table lists the variables to be imported: 'depth', 'latitu...', 'longi...', 'salinity', and 'temp...'. Each variable is checked in the 'Import' column and is identified as a 'double' type. The 'Finish' button is highlighted.

Import	Name ^	Size	Bytes	Class
<input checked="" type="checkbox"/>	depth	3605x1	28840	double
<input checked="" type="checkbox"/>	latitu...	3605x1	28840	double
<input checked="" type="checkbox"/>	longi...	3605x1	28840	double
<input checked="" type="checkbox"/>	salinity	3605x1	28840	double
<input checked="" type="checkbox"/>	temp...	3605x1	28840	double

After the process is finished, the ensuing visuals will be showcased. These encompass TS profiles, TS diagrams, and their corresponding  $\sigma$ - $\pi$  diagrams.

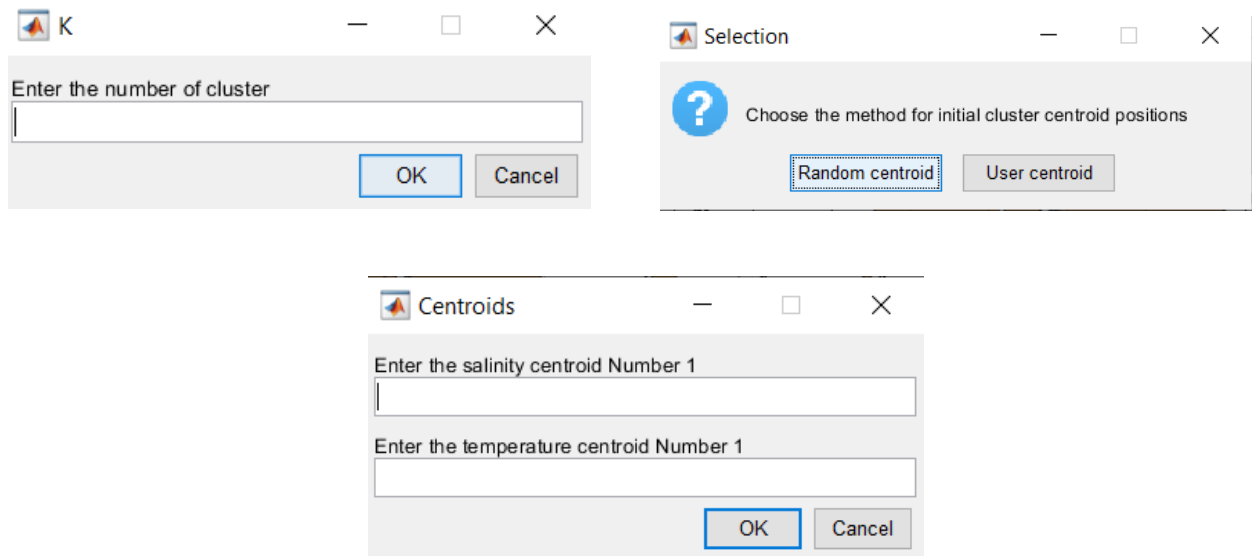

Also, the geographic coordinates of the profiles are depicted on the map. To restrict the geographical scope, the user enters the boundary parameters and confirms the selection. The global map is re-displayed upon clicking the restore button.

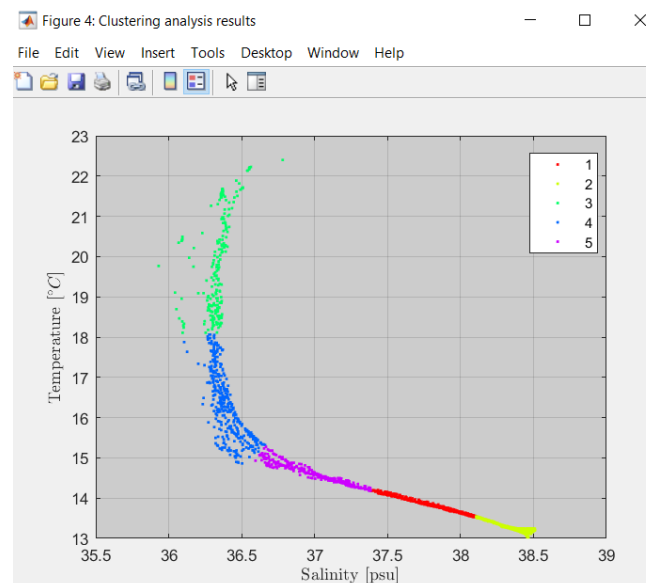

## k-means

This functionality is employed to implement the k-means algorithm on the imported dataset. The user selects the desired number of clusters and subsequently specifies the method for centroid selection. Opting for the 'Random centroid' entails initializing k-means with randomly chosen centroids. Conversely, opting for 'User centroid' offers the user the opportunity to define temperature and salinity values for centroids.

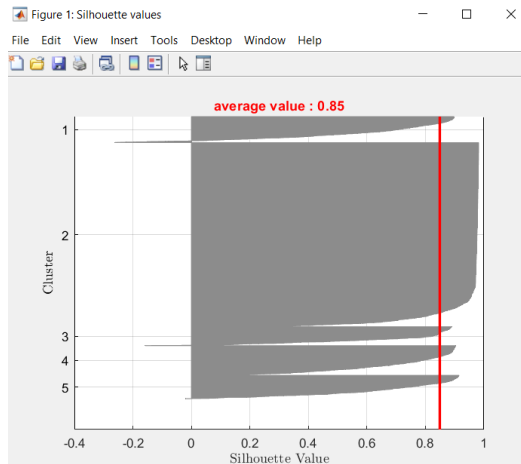

Following confirmation, the interface produces the outcome of water mass classification, presented in the format of a TS diagram.

## Silhouette plot

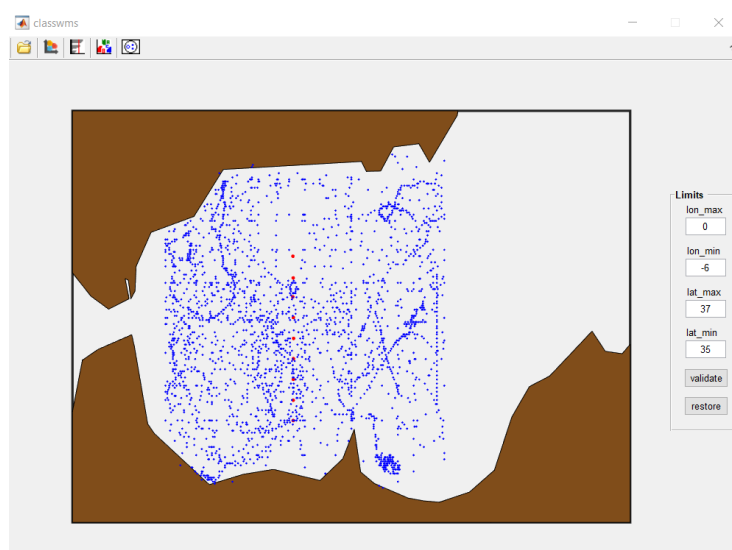

Silhouette values can be graphed through 'Silhouette plot' button, to visually evaluate the selected number of clusters.

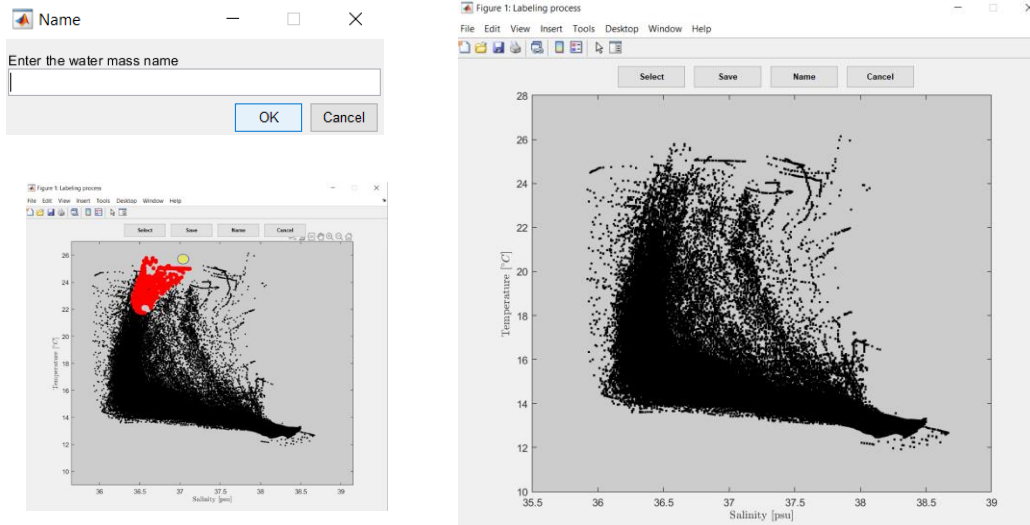

## Labeling process

This functionality is employed for importing the user-designated database file. The file, referred to as 'database\_not\_labeled.txt', comprises the subsequent fields: longitude, latitude, depth, temperature, and salinity. The import procedure for this file resembles that of the 'data\_to\_classify.txt' file.

Also, the geographic coordinates of the database profiles are plotted on the map. To restrict the geographical scope, the user enters the boundary parameters and confirms the selection. The global map is re-displayed upon clicking the restore button.

After that, an interactive window appears to allow labeling.

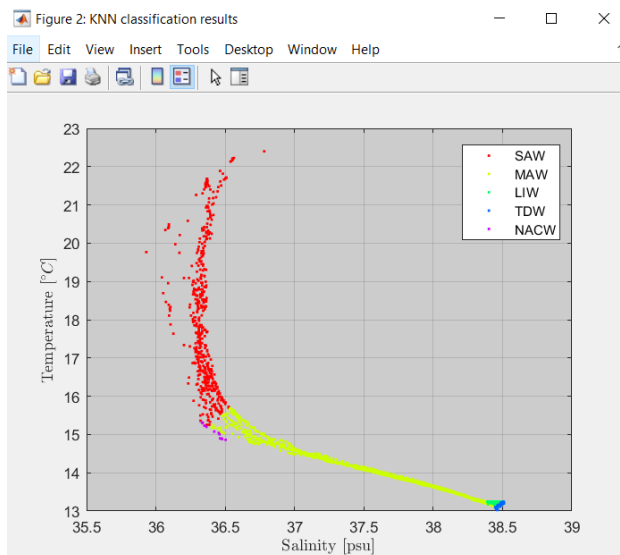

Initially, the user selects the water mass's name for labeling and subsequently initiates the process of sample selection associated with that particular water mass. Upon clicking the 'save' button, the data undergoes conversion into a potential density and potential spicity ( $\sigma$ - $\pi$ ) diagram, after which it is stored in a file encompassing the subsequent attributes: spi, sigma, WM. This procedure needs to be reiterated based on the count of distinct water masses. All the saved files can be found within the directory 'C:\classwms\data'.

Upon completing this process, the user should combine the individual files for each water mass into a single file named 'database\_labeled.txt', which should include a header comprising the fields: PI, SIGMA, NAME and placed in the directory 'C:\classwms\data'.

### KNN classifier

This feature is utilized to implement the k-nearest neighbors (knn) algorithm for the classification of water masses. The prepared labeled database file is imported automatically, initiating the training process. Subsequently, confusion matrix charts are generated, and the interface produces the results of water mass classification in the form of a TS diagram.

#### 4. DATA REFERENCES

- The 'data\_to\_classify.txt' file, contains a hydrographic (CTD) cast of an intensive oceanographic survey (BIOMEGA) collected on board of the Spanish R/V Garcia del Cid during October 2003. Data were provided through SeaDataNet Pan European infrastructure for ocean and marine data management (<https://www.seadatanet.org>).
- The 'database\_not\_labeled.txt' file, contains in-situ observations from oceanographic databases such as World Ocean Database 2018 ' WOD18' and the Global Data Assembly Centers ' GDACs.
